MAAM-011109-DIE

Wideband Amplifier
DC - 50 GHz

Rev. V3

Features
- 15 dB Gain
- 50 Ω Input / Output Match
- 20 dBm Output Power
- 5 V DC, 190 mA
- Die size: 1.97 x 1.30 x 0.1 mm
- Gold-Plated Contact Pads, Backside
- 100% On-Wafer DC & RF Tested
- RoHS* Compliant

Description
The MAAM-011109-DIE is an easy-to-use, wideband amplifier that operates from DC - 50 GHz. This device features 15 dB gain and +20 dBm of output power. Matching is 50 Ω with typical return loss better than 15 dB. This amplifier requires dual DC power supplies: 5V (190 mA) and a low current negative VG1 (< 1 mA).

Features include gate bias adjust to change current setting for power or temperature, gain trim control that allows 15 dB of gain control (0 to -1 V), and a temperature-compensated detector that provides a DC voltage in relation to the output power.

The MAAM-011109-DIE is ideally suited for any application that requires 50 Ω gain from DC to 50 GHz. It is useful in circuits where the incoming signal varies over a broad bandwidth such as laboratory, instrumentation, and defense applications.

5. Exceeding any one or combination of these limits may cause permanent damage to this device.

6. MACOM does not recommend sustained operation near these survivability limits.

7. Operating at nominal conditions with \( T_J ≤ +150°C \) will ensure \( MTTF > 1 \times 10^6 \) hours.

8. Junction Temperature (\( T_J \)) = \( T_C + \Theta_{jc} \times (V \times I) \)

Typical thermal resistance (\( \Theta_{jc} \)) = 17.8°C/W.

a) For \( T_C = 25°C \),
\[ T_J = 47°C @ 6.5V, 190mA \]
b) For \( T_C = 85°C \),
\[ T_J = 107°C @ 6.5V, 190mA \]

Handling Procedures

Please observe the following precautions to avoid damage:

Static Sensitivity

These electronic devices are sensitive to electrostatic discharge (ESD) and can be damaged by static electricity. Proper ESD control techniques should be used when handling these Class 1A devices.

Application Information (DC & Pads)

For proper operation a DC voltage must be applied to the VG1 (typically -0.4 V) and OUT (typically +5 V) pads in that order. Note that the Biasing Schematic shows ESD diodes connected to the VC and VG1 pads (the notation (4) on the VC pad indicates there are four forward diodes in series and the (2) on the VG1 pad diode indicates there are two reverse diodes in series).

Adjusting VG1 from -1.0 to -0.2 V will increase the quiescent current. The actual operating voltage should be kept between 3.3 and 6.5 V for proper operation.

The VG1 and VD pads should be bypassed with 0.22 µF for flattest overall low end response. Best flatness for 1 GHz and above will be achieved by bypassing the VD1 pad, instead of the VD pad, with at least 150 pF and a total trace plus bondwire inductance of 2.5 nH, and the VG1 pad with at least 150 pF.

Bandwidth, Power, Noise and Linearity

Bias voltage and current affect both the bandwidth (response flatness), power available, noise figure, and linearity of the amplifier. Higher currents and lower bias voltage increase high frequency gain but reduce the P1dB and the OIP3 numbers. If the device is driven to P1dB and on into Psat the bias current will naturally reduce. The device will return to the quiescent current value once the input power is reduced. Finally, higher bias current values increase the device noise figure.

Temperature also affects the bandwidth, gain and noise figure of the device. Lower temperatures increase gain and bandwidth but reduce the noise figure. Temperature has little effect on power and linearity.

1. All units are in µm, unless otherwise noted, with a tolerance of ±5 µm.
2. Die thickness is 100 ±10 µm.
**Broadband Amplifier Applications**

The MAAM-011109-DIE also has a low enough noise figure to be used in instrumentation front ends and buffer applications. It also has very flat response with low group delay distortion so it can be used in pulse applications. For higher gains multiple amplifiers may be cascaded. It also makes a very good low cost optical driver capable of delivering up to 8 V p-p into 50 ohms.

**Variable Gain/Limiting Applications**

The gain of the MAAM-011109-DIE can be easily controlled with the VC pin. The gain reduction is almost linear with VC between 0.1 V to -0.8 V. Below -0.7 V internal ESD protection diodes will draw increasing current (50 mA at -1.0 V). The VC pad should not be driven below -1 V or above 1.2 V. The nominal open circuit voltage at the VC pad is 0.8 V.

Reducing VC below 0.8 V will also reduce the bias current. Gain, P1dB, and PSAT will all be reduced as the voltage on VC is lowered. Limiting applications and zero crossing adjustment can be done by adjusting the VG1 and VC pads together.

**Internal Detector**

The VDET pad is connected to an internal diode detector. This pad should be connected to a high impedance (>50 kΩ) or left unconnected. The detector is internally connected so that it responds predominately to the power generated by the amplifier and is temperature compensated. The detector has a low pass characteristic which rolls off gradually above 1 GHz. Finally, even with zero output power the detector has a DC output voltage proportional to the bias voltage (nominally 2.8 V for 5 V at the OUT pad).
